

1. Here are some axioms that the rule **obeys** :

It obeys the Pareto principle (#3 in the text) : if every person preferred  $A$  to  $B$ , that means 100% prefer  $A$  to  $B$ , which is certainly more than 80%; so whenever  $A$  is preferred unanimously to  $B$ , it will be ranked higher than  $B$ .

It is non-dictatorial (#6 in the text) : if one person prefers  $A$  to  $B$ , and everyone else prefers  $B$  to  $A$ , then  $A$  will **not** be ranked above  $A$ .

Independent alternatives are irrelevant (#5 in the text) : the ranking of  $A$  and  $B$  depends only on how people rank those alternatives relative to each other, not on how they rank either of them compared to some third alternative  $C$ .

But it certainly violates transitivity (#4 in the text), for example if people's preferences over 3 alternatives  $a$ ,  $b$  and  $c$  are as described in the table below :

1	2	3
$a$	$a$	$b$
$b$	$c$	$a$
$c$	$b$	$c$

Since only two-thirds of the people prefer  $a$  to  $b$ ,  $a$  and  $b$  are ranked as tied. Since only two-thirds of the people prefer  $b$  to  $c$ ,  $b$  and  $c$  are ranked as tied. But 100% of the people rank  $a$  above  $c$ , so that  $a$  and  $c$  are not tied, which means that the social ranking is not transitive.

It also does not always produce a top-ranked alternative ( that is, #1 in the text can be violated ). In the following example,  $a$  is ranked above  $b$  which is ranked above  $c$  which is ranked above  $d$  which is ranked above  $e$  which is ranked above  $f$ , but  $f$  is ranked above  $a$ . ( This example also shows that the rule is not transitive. )

1	2	3	4	5	6
$a$	$b$	$c$	$d$	$e$	$f$
$b$	$c$	$d$	$e$	$f$	$a$
$c$	$d$	$e$	$f$	$a$	$b$
$d$	$e$	$f$	$a$	$b$	$c$
$e$	$f$	$a$	$b$	$c$	$d$
$f$	$a$	$b$	$c$	$d$	$e$

2. Voter #1 is the voter who likes alternative  $a$  the most. So she would like to find a rule that guarantees a win for  $a$ .

So first she should find out what alternatives  $a$  can beat in a two-way vote. From the table,  $a$  can beat  $b$  in a two-way vote ( voters #1 and #3 prefer  $a$  to  $b$  ), and it can defeat  $d$  ( voters #1 and #2 prefer  $a$  to  $d$  ). But it would lose to  $c$  in a two-way vote, since both voters #2 and #3 prefer  $c$  to  $a$ .

Voter #1, when organizing the votes, wants to make sure that  $a$  does not get matched up against  $c$  in the first stage, since  $a$  would lose. So she should match  $a$  against  $b$  or  $d$  in the first stage.

But she also wants  $a$  to win the second stage, which means that she has to ensure that  $c$  does not win the first stage ( because it would then beat  $a$  in the second stage ). So she has to find an alternative that two out of three voters prefer to  $c$ . From the table, that's  $b$  : voters #1 and #2 will both vote for  $b$  over  $c$ . ( But  $d$  will lose to  $c$  in any vote. )

What she should do is match  $a$  against  $d$ , and  $b$  against  $c$ , in the first stage.  $a$  and  $b$  would win those first votes, and then  $a$  would defeat  $b$  in the second stage. That way is the only way of getting  $a$  to win both votes, if people vote sincerely.

But they won't want to vote sincerely. Consider person #2, who ranks  $a$  fairly low. In the first stage, he would vote for  $b$  over  $c$ , and  $a$  over  $d$  if he voted sincerely, only to see  $b$  lose to  $a$ . If others voted sincerely, he would be better voting strategically, voting for  $d$  over  $a$  in the first stage, even though he actually ranks  $a$  higher than  $d$ .

Why should he vote for  $d$  in the first stage? That would make  $d$  win the first stage ( since if voter 3 votes sincerely, she votes for  $d$  over  $a$  ). Assuming that everyone voted sincerely in the other first stage election ( so that  $b$  beat  $c$  ), this strategic behaviour would set up a second-stage vote between  $b$  and  $d$ , which would be won by  $b$ , voter #2's overall favourite.

Therefore, strategic voting leads to a more attractive outcome, from voter #2's point of view : sincere voting leads to an outcome of  $a$ , and strategic voting leads to an outcome of  $b$ , his most preferred outcome.

3. If a voter has income of 24, and expects to pay for one-third of the cost of highways and education, then her private food expenditure  $x_i$  would equal  $24 - (H + E)/3$ . So her overall utility if a policy  $(H, E)$  were implemented would be

$$24 - \frac{H + E}{3} + a_i \ln H + b_i \ln E$$

To find the policy she would like best, take the derivatives with respect to  $H$ , and with respect to  $E$ , and set them equal to 0.

The derivative with respect to  $H$  is

$$-\frac{1}{3} + \frac{a_i}{H}$$

which equals zero when  $H = 3a_i$ . The derivative with respect to  $E$  is

$$-\frac{1}{3} + \frac{b_i}{E}$$

which equals zero when  $E = 3b_i$ .

Therefore, each voter's preferred policy is  $(3a_i, 3b_i)$ . So voter #1 wants (18, 18), voter #2 wants (9, 6) and voter #3 wants (3, 27).

4. Suppose that highway expenditure  $H$  varies, holding constant education expenditure  $E$ . If voter  $i$  pays for  $1/3$  of the cost of the highway expenditure, then her utility is  $24 - (H + E)/3 + a_i \ln H + b_i \ln E$ . Question #3 showed that the derivative of this utility with respect to  $H$  is

$$\frac{a_i}{H} - \frac{1}{3}$$

This derivative is positive whenever  $H < 3a_i$ , and is negative whenever  $H > 3a_i$ . Therefore, her preferences are single-peaked, with a unique local maximum at  $H = 3a_i$ . Similarly, the derivative with respect to  $E$  is  $b_i/E - 1/3$ , which is positive when  $E < 3b_i$  and negative when  $E > 3b_i$ , and so is single-peaked.

If people vote over highway expenditure, the single-peaked preferences imply that the median of the preferred levels  $3a_i$  of highway expenditure will win, namely  $H = 9$ . If they vote over education expenditure, then the median preferred level of  $3b_i$ ,  $E = 18$ , will win.

So the likely outcome is  $(H, E) = (9, 18)$ . Any proposal to change  $H$  from 9, or to change  $E$  from 18, will lose. ( For example, voters 1 and 2 would vote against any proposal to lower  $H$  below 9, and voters 2 and 3 would vote against any proposal to increase highway expenditure above 9. )

5. Let  $T$  be total expenditure, and let  $h$  be the fraction of total expenditure spent on highways, so that  $H = hT$  and  $E = (1 - h)T$ . Now  $x_i = 24 - T/3$ , and a voter's utility can be written

$$24 - \frac{T}{3} + a_i \ln hT + b_i \ln (1 - h)T$$

The derivative of this utility with respect to  $T$  is

$$-\frac{1}{3} + \frac{a_i}{T} + \frac{b_i}{T}$$

This expression is positive whenever  $T < 3(a_i + b_i)$ , and negative whenever  $T > 3(a_i + b_i)$ . Therefore, in voting over total expenditure  $T$  ( taking as given the share  $h$  going to highways ), each voter has single-peaked preferences, with a peak at  $3(a_i + b_i)$ . The median voter theorem applies, and the winning level of total expenditure  $T$  is the median of the preferred levels  $3(a_i + b_i)$ , in this case  $T = 30$ . Any increase in  $T$  above 30 would be opposed by a coalition of #2 and #3 ; any proposal to decrease  $T$  below 30 would be defeated by a coalition of #1 and #3.

The derivative of utility with respect to the share  $h$  of expenditure going to highways is

$$\frac{a_i}{h} - \frac{b_i}{1 - h}$$

This derivative is positive whenever  $h < a_i/(a_i + b_i)$ , and negative whenever  $h > a_i/(a_i + b_i)$ . Thus preferences for each voter, over the share of expenditure going to highways, are single-peaked, with a peak at  $h = a_i/(a_i + b_i)$ . The median voter theorem applies : here  $a_i/(a_i + b_i)$  equals  $1/2$ ,  $3/5$  and  $1/10$  for the three voters. The median level is  $1/2$ . Therefore, spending exactly half the budget on highways will defeat any other proposed share,  $h = 1/2$  is the winner.

Therefore, in this case, the likely outcome is  $T = 30$  and  $h = 1/2$ , meaning that  $H = 15$  and  $E = 15$ . Notice that this is a different outcome than would occur if voters voted on  $H$  and  $E$  separately, as in question #4.
