

The Periodic Table and Atomic Properties

- The periodic table originally came from the observation that when the elements are arranged by **atomic mass**, properties recur periodically. (**Mendeleev**)
- Now we understand the periodic table in terms of **atomic number** and electronic structure.
- We will look at the properties of elements from this viewpoint.

CHEM 1000 3.0

Atomic theory and the
Periodic table I 54

Metals and Nonmetals

- Metals have the properties:
 - Good conductors of heat and electricity
 - Malleable and ductile
 - High melting points
- Non-metals have the properties:
 - Poor conductors of heat and electricity
 - Brittle
 - Low melting points (some are even gases at room temperature)

Metals and Nonmetals																	
Non metals:									Metals								
Metalloids									In between metal and non-metals								
• Non metals:									• Metals								
– To the right of the periodic table									– Most elements are metals								
– Includes the noble (inert) gases as a special case									• Metalloids								
– In between metal and non-metals, have some properties of metals and non-metals																	
CHEM 1000 3.0									Atomic theory and the Periodic table I 56								

Correlations between electronic configuration and properties

- Noble Gases:
 - All have a full valence shell
 - This gives extreme stability and chemical inertness
- It appears most elements try to achieve this stability by acquiring or losing electrons

CHEM 1000 3.0

Atomic theory and the
Periodic table I 58

Group 1 and 2 metal ions

- These have 1 or 2 electrons more than a Noble gas
 - They can lose these electrons (through reaction for example) to produce very stable ions
 - Aluminum (Group 13) will actually lose 3 electrons to achieve the stable ion

CHEM 1000 3.0

Atomic theory and the
Periodic table I 59

CHEM 1000 3.0

Atomic theory and the
Periodic table I 62

Transition Metal Ions

- The electrons are lost from Transition metals in a **different order than the aufbau principle** would suggest
 - **They lose the “s” orbital electrons first**
 - Often they also lose “d” orbital electrons to give a half filled “d” subshell which has special stability.
 - e.g Fe [Ar]3d⁶4s² gives Fe³⁺ [Ar]3d⁵

CHEM 1000 3.0

Atomic theory and the
Periodic table I 63

Sizes of Atoms and Ions

- Atomic and ionic radii cannot easily be described as the electron density extends to infinity
- Usually we use the measured distances in compounds to infer sizes, but even these are not all the same

CHEM 1000 3.0

Atomic theory and the
Periodic table I 64

Sizes of Atoms and Ions

- Definitions
 - Covalent radius
 - Half the distance between identical atoms in a covalent compound
 - Ionic radius
 - Determined from separation between ions joined by ionic bonds
 - Metallic Radius
 - Half the distance between metal atoms in crystalline solid

CHEM 1000 3.0

Atomic theory and the
Periodic table I 65

Sizes of Atoms and Ions

Covalent radius:

Metallic radius:

Ionic radius:

CHEM 1000 3.0

Atomic theory and the
Periodic table I 66

Sizes of Atoms and Ions

Can we explain this variation in radii?

- Down a group radii increase
- Across a period radii decrease
- Transition metal radii don't change much

CHEM 1000 3.0

Atomic theory and the
Periodic table I 67

Sizes of Atoms and Ions

Copyright © 2007 Pearson Prentice Hall, Inc.

- Within (Down) a Group
 - The probability of finding an electron at larger distances is higher for higher n
 - Hence the more electronic shells the larger the atom

CHEM 1000 3.0

Atomic theory and the
Periodic table I 68

Sizes of Atoms and Ions

CHEM 1000 3.0

Atomic theory and the
Periodic table I 69

Sizes of Atoms and Ions

- Across a period
 - The nuclear charge and the number of electrons increase while the *n* stays the same.
 - Across a period the electrons go into the outer orbitals. The amount of screening is about the same, so successive electrons see higher effective nuclear charges so **the radius decreases across a period.**

CHEM 1000 3.0

Atomic theory and the
Periodic table I 70

Sizes of Atoms and Ions

- Across a period (ctd)
 - The nuclear charge and the number of electrons increase while the *n* stays the same.
 - For transition metals the electrons are going into an INNER shell so the screening is more pronounced. The number of outer shell electrons stays the same. The increase in the nuclear charge is balanced by the increased screening. The outer electrons see the same effective nuclear charge. Since the size is determined by the outer electrons **the radius remains similar across a transition metal series**

CHEM 1000 3.0

Atomic theory and the
Periodic table I 74

Ionization Energy

- The ionization energy (IE) is the energy required to remove an electron to make an ion (+).
 - The further an electron is from the nucleus the lower the energy needed to completely remove it. **Ionization energies decrease as ionic radii increase**

CHEM 1000 3.0

Atomic theory and the
Periodic table I 75

Ionization Energy

- The ionization energy (IE) is the energy required to remove an electron to make an ion (+).
 - There are 2nd and 3rd ionization energies to remove successive electrons. Since the ion is smaller than the atom and there is a net charge, the successive IEs are higher

CHEM 1000 3.0

Atomic theory and the
Periodic table I 76

Electron Affinity

- The electron affinity (EA) is the energy change when an atom gains an electron to make an ion (-).

The atom releases energy when it gains the electron

- Atoms that have high EA are those where adding an electron stabilize a shell
 - Group 17 elements gain an electron to fill the shell
 - Group 1 elements gain an electron to fill the “s” orbital

CHEM 1000 3.0

Atomic theory and the
Periodic table I 78

Magnetic Properties

- An atom will only respond significantly to a magnetic field if it has a magnetic field itself.
– This means it must have an unpaired electron (or more)
- In a **diamagnetic** atom all electrons are **paired** and it is weakly **repelled by a magnetic field** e.g. Mg
- A **paramagnetic** atom has **unpaired** electron(s) and it is **attracted by a magnetic field** e.g. Na
