## Abstract

A model mechanism for the phenol-inhibited peroxidase-catalyzed oxidation of indole-3-acetic acid (IAA) is proposed and analyzed. The model involves an autocatalytic free radical species that sustains IAA oxidation and the phenolic inhibitor acting as a free radical scavenger. Under a fixed set of parameter values, the model exhibits a coexistence of two stable steady states. This bistability phenomenon explains the origin of the experimentally observed threshold inhibitor concentrations above which IAA oxidation stops. The variation of the inhibitor threshold level with enzyme and substrate concentrations are reproduced by the model almost quantitatively.

*Keywords:* Oxidation of indole-3-acetic acid; Phenol inhibition mechanism; Reaction threshold; Bistability; Modelling; Computer simulation

## 1. Introduction

Indole-3-acetic acid (IAA) is a natural phytohormone with many growth regulatory functions. The concentration level of IAA in plants depends, in particular, on the rate of its oxidation which is catalyzed by IAA-oxidases, many of which are peroxidases. The rate of the peroxidase-catalyzed oxidation of IAA is affected by natural phenolic inhibitors such as caffeic acid, gallic acid, chlorogenic acid, and others.

In this paper, we propose a model mechanism of phenol inhibition to explain the experimental observations reported earlier [1,2]. Previous investigators [3–8] have suggested that phenols inhibit the peroxidase-catalyzed oxidation of IAA by acting as competing substrates for the enzyme. Reported Lineweaver–Burk plots [5,9], however, are inconsistent with a competitive inhibition mechanism. Our proposed model suggests that phenols inhibit IAA oxidation by scavenging the free radicals that drive the peroxidase-catalyzed reaction.

It was found in previous experiments [1] that, under some conditions, a well-defined level of inhibitor concentration exists above which IAA oxidation stops. Below this threshold inhibitor concentration, the oxidation rate is almost unaffected. Analysis of our model mechanism provides a clear explanation of the origin of this threshold concentration. The model exhibits a coexistence of two stable steady states, one of which corresponds to the inhibited reaction while the other corresponds to the un-in-
